

Cancer Survivors Are Less Likely to Use Marijuana Than the General Public

Over four years, 9% of cancer patients used marijuana, compared with 14% of people who didn't have cancer, finds a national study.

September 6, 2021 By [Trent Straube](#)

Despite the growing legalization and social acceptance of marijuana, people with [cancer](#) reported using less cannabis than the general population with no cancer history. However, cancer survivors were more likely to use [marijuana](#) if they were younger, didn't have health insurance or experienced greater levels of [pain](#).

Specifically, researchers from the [Massey Cancer Center at Virginia Commonwealth University](#) found that between 2013 and 2018, a peak of 9% of cancer patients reported using marijuana, compared with 14% of folks with no history of cancer. The results of their study were [published in the journal Cancer](#).

During the study period, cannabis use among people with no history of cancer increased, while the use among cancer survivors remained the same. Why the difference in the two groups?

"There is that element of a life-changing moment when you have cancer," lead author [Bernard Fuemmeler, PhD](#), associate director for population science and interim coleader of the [Cancer Prevention and Control](#) research program at Massey Cancer Center, [told VCU News](#). "You have to be mindful of your health and contemplate whether something like cannabis is helpful or hurtful."

To determine the prevalence of cannabis use, the researchers looked at data from the Population Assessment of Tobacco and Health study, a nationally representative survey. From that pool, they looked at data from 1,022 people who reported a cancer diagnosis and 19,702 people who never reported having cancer during the four-year period.

The researchers found that people in both groups were less likely to use marijuana if they were older and had health insurance. Among cancer survivors, those who experienced more pain were more likely to use cannabis. And among people with no history of cancer, individuals were less likely to use marijuana if they were female, white and had a better mental health status.

"Although cannabis use prevalence is lower among cancer survivors, the reasons for use are not markedly different from those without a cancer history," conclude the researchers. "Continued

monitoring of use, reasons for use, and harms or benefits is warranted.”

In related news, a 2017 survey of cancer patients at a cancer center in Washington state, where pot is legal, found that nearly [25% of respondents reported using cannabis](#).
